

Dr. Jorden Senior

Experimental Quantum Shutterbug

10.11.2024

Biography

Dr. Jorden Senior is a Research Team Leader in Quantum Computing Hardware at VTT Technical Research Centre of Finland, where he leads groundbreaking projects focused on developing next-generation quantum technologies.

To complement his scientific pursuits, Dr. Senior is a passionate experimental photographer exploring analogue processes and new materials. His artistic practice is characterized by a fascination with the interplay of light, texture, and chemistry, resulting in unique photographic works that challenge conventional perceptions of technology and art. Through experimentation with lith printing and other traditional methods, he captures the essence of his subjects, evoking a sense of timelessness and depth.

Based in Helsinki, Finland, Dr. Senior integrates his dual passions for quantum computing and analogue photography, believing that the two disciplines can inform and inspire one another. His exhibitions and workshops not only showcase his artistic vision but also foster discussions around the connections between scientific innovation and creative expression. By bridging the gap between cutting-edge technology and the rich heritage of photographic art, Jorden continues to contribute to both fields, inspiring others to explore the dynamic interplay between art and science.

Artist Statement

My work explores the intersections between the most cutting-edge frontiers of technology and traditional photographic printmaking. As a Europe-leading expert in experimental quantum computing—a field that challenges our fundamental understanding of reality, increasingly defined by digital precision and impermanence, I turn to analogue techniques such as lith printing to capture the intricate, almost organic nature of quantum machines, and modern society, in ways that feel timeless and tangible.

Each piece in my collection aims to reimagine quantum technology and urban landscapes as something both futuristic and primal. Using lith printing, with its grainy textures, deep contrasts, and warm tones, I translate observations in my surroundings into visual artifacts that feel both ancient and mythological. This analogue approach introduces an unpredictable quality that mirrors the uncertainty and beauty of quantum physics itself, blending grain with digital symmetry, and dark shadows with glowing highlights.

By capturing the hidden, almost poetic structures of modern technology through lith, I invite viewers to experience these machines and structures not just as symbols of progress, but as mysterious, almost spiritual relics. In this way, my work bridges the past and the future, the organic and the artificial, offering a moment to contemplate the essence of technology through an analogue, human lens.

Quantum Photo-chemical decay

In a recent project, I started exploring using the Mordencage process to induce chemical entropy into my photographic prints, lifting the emulsion from the paper and inducing distortions, a visceral chemical decay directly onto the print itself.

As part of the project, I also produced a small volume zine using a Helsinki-based Risograf.

Colour-Mordençage Process

I am currently developing a mordençage process for the RA-4 colour printing process, to induce chemical decay into colour images, bringing out the colour layers in the print, to enhance the image. Colour and dynamism that was always there, just hidden.

Found Media Lumen Lith Prints

The method in Lith printing can be simplified as over-expose, then weakly develop until done. In this series of works, I have experimented with using found media (magazines, newspapers, etc) in contact with photosensitive paper exposed with room light, in the typical 'lumen' print way - but then developed using the Lith method. This allows for significantly more tones and smooth textures in the print, with a unique look that would be challenging to achieve otherwise.

Enhancements through imperfections

The long development times involved in Lith printing encourage the printer to monitor the print, and stop the development when the time is right. With the blacks coming through significantly earlier than the midtones, this can lead to an image where one can have a smooth blend into the highlights.

(Selectively) Imperfect development can lead to 'snowballs', which are usually to be avoided. In some cases, such as the print on the left - they add an almost fantasy element - the tradesmen ascending into the clouds - completely changing the feeling from the original negative (right)

From smooth to contrast

These two shots are subsequent frames from the same roll, in the same location, with very similar lighting conditions - but printed in two different extremes of the Lith process.

The print on the left uses a very slow development process, to bring out the midtones and gives an incredibly smooth image. The print below, however, focuses purely on contrast, providing extremely rich blacks in the shadows, with enough midtones to understand the forms, but no more.

Exhibitions and Projects

- ❖ Co-exhibitor - 'From the very big, to the very small', Lancaster, UK (2014)
- ❖ Co-exhibitor & demonstrator - 'From the very big, to the very small', Holster Garden Show, UK (2015)
- ❖ Co-exhibitor - IBM Quantum Arcade, Boston, USA (2019)
- ❖ Co-curator - Quantum Experience, Helsinki / Espoo Finland (2020)
- ❖ Co-exhibitor & -curator - Pimiö25, Helsinki (2025)
- ❖ Various mentoring and judging roles in game jams (2016 - present)

Contact
